Table of Contents

1. Test Results Overview

- Summary of test case statuses
- Observations from the test execution

2. Test Results Analysis

- Analysis of test performance
- Discussion of any failed test cases
and possible resolutions
- Evaluation of functional correctness
and system behavior

3. Logs and Outputs

- Authentication logs (Firebase)
- Console logs and UI interaction
results

4. Abstract

Test Results Overview

Test Case	Status	Notes
User Registration Test	Pass	Users can successfully create an account using Firebase Authentication new user appears correctly in the Authentication Users panel.
User Login Test	Pass	Users can log in with valid credentials and are redirected to the dashboard without errors.
Schedule Management Test	Pass	Users can add, update, and delete schedule slots, and all changes are correctly stored and reflected in Firestore.
Free-time Matching Test	Pass	The system accurately detects overlapping free time slots and displays matching students filtered by the selected dining venue.

Test Results Analysis

- All acceptance tests passed successfully, demonstrating correct functionality across user authentication, schedule management, and free-time matching. The system behaved consistently with the defined acceptance criteria.
- The Schedule Management Test showed that adding, updating, and deleting weekly schedule entries works reliably. All modifications were correctly written to Firestore, and the UI accurately reflected the latest stored data.
- The Free-time Matching Test also performed as expected. The matching algorithm successfully calculated overlapping free time intervals between users and filtered results based on the selected dining venue. Cases where no matching students were found correctly triggered the “Match Unavailable” message.
- No critical functional failures were detected during testing. Minor UI timing delays were observed during Firestore reads, but these did not impact the correctness of the matching process and can be improved later through optimization.

Logs and Outputs

- Firebase Authentication logs confirm successful account creation and login attempts. Both valid and invalid login scenarios were logged correctly, showing proper handling of authentication states.
- Firestore logs show accurate read/write operations during schedule management. Added, updated, and deleted schedule entries were reflected immediately in the database, and no unauthorized write attempts were detected.
- Console logs demonstrate that the free-time matching function retrieved all user schedules correctly, calculated overlapping time slots as expected, and applied venue-based filtering without errors. “Match Unavailable” messages were logged properly when no matching users were found.

Abstract

Synkly is a web-based scheduling tool designed to assist university students in identifying overlapping free time intervals and viewing potential meeting opportunities based on selected campus dining venues. The system uses Firebase Authentication to ensure secure access control and Firestore as the primary database for managing user schedules and related data. The project aims to provide a clear and intuitive interface for editing weekly schedules, synchronizing data in real time, and displaying time-slot overlaps efficiently. Testing confirmed that the implemented features such as user registration, login, schedule management, and free-time matching function as intended and meet the established acceptance criteria. Future development may focus on improving interface responsiveness, refining database operations, and expanding the system to support additional campus-related use cases.
